Projeto em Engenharia Informática, 3º ano, LEI.

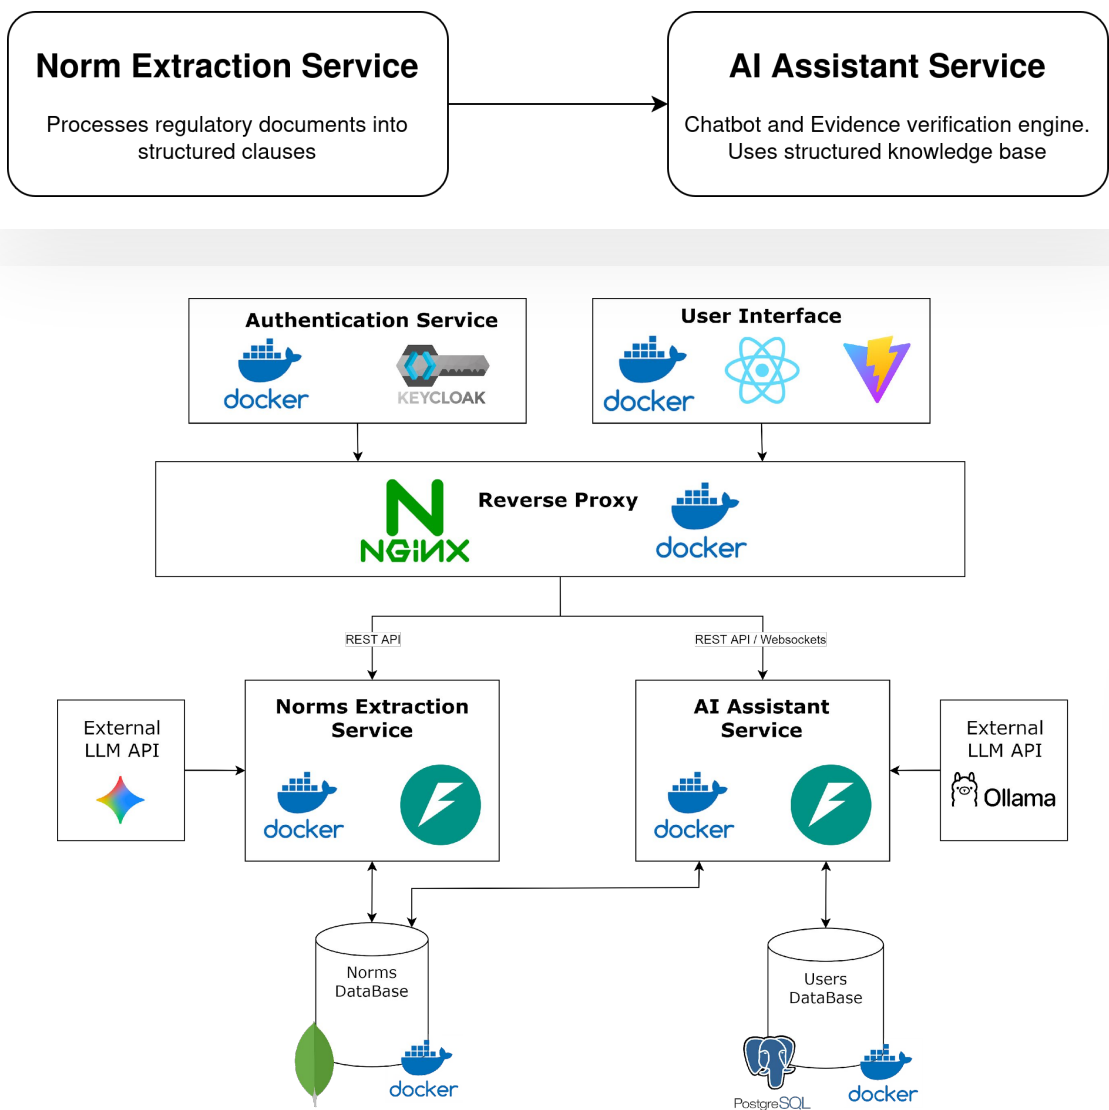

2026

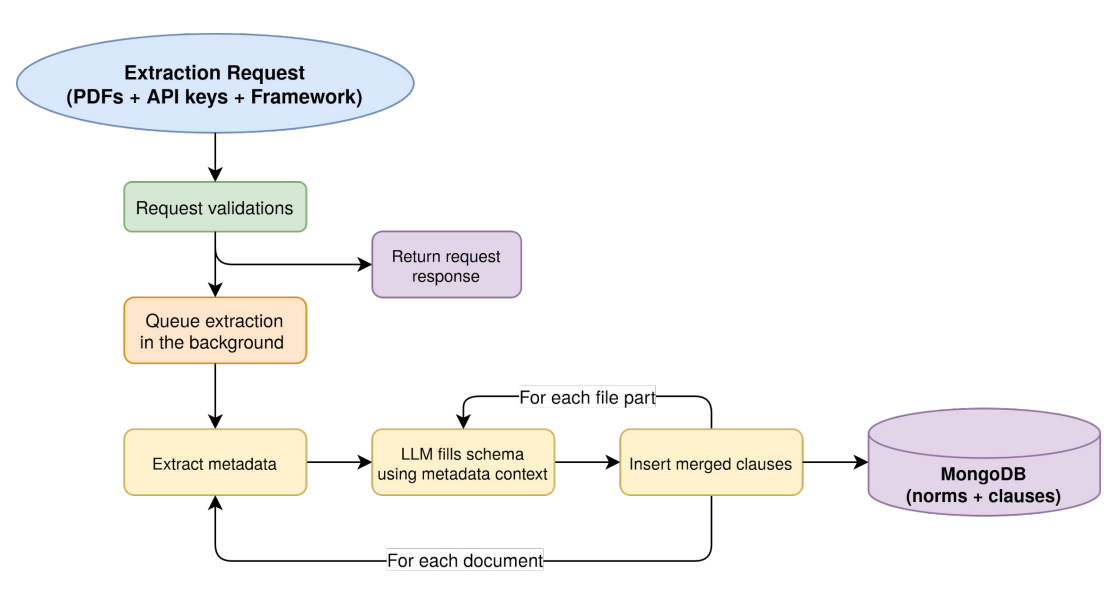

CertiBot is an AI-powered assistant that guides organizations through the adoption of compliance standards, from understanding requirements to verifying implementation.

Methods

CertiBot's backend consists of two core components:

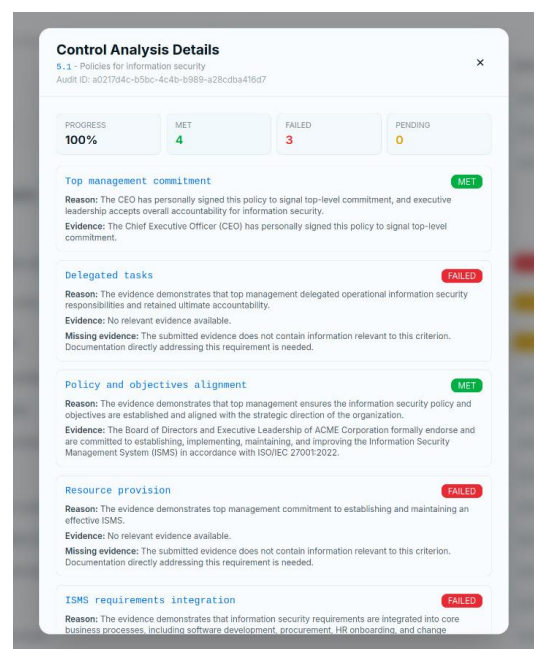

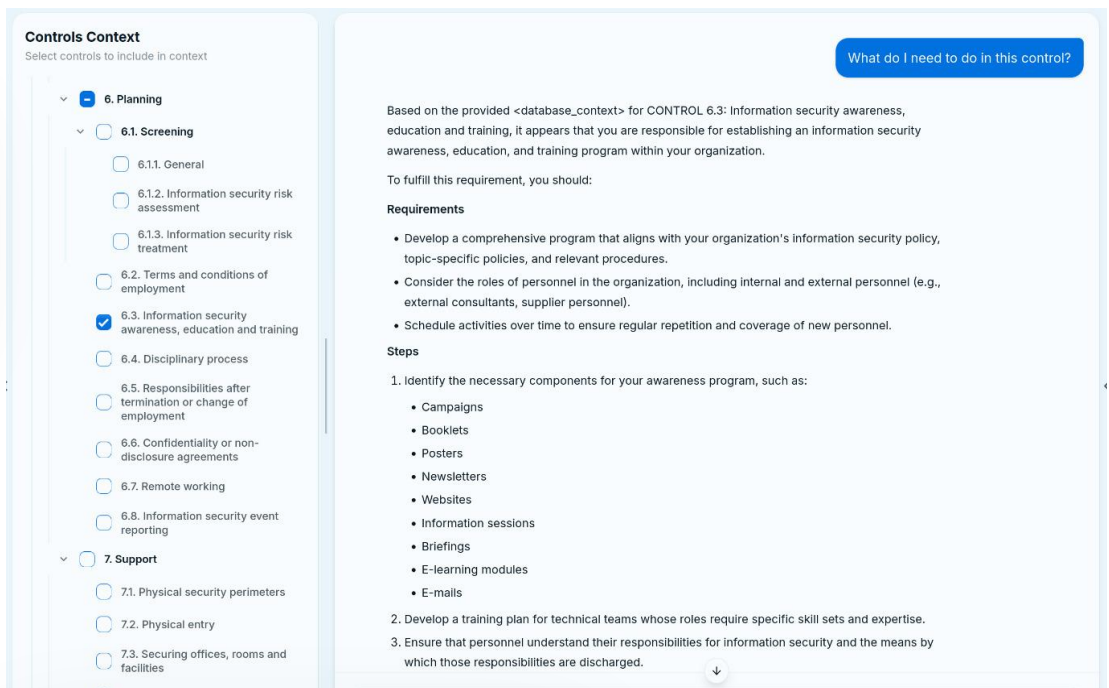

The processing of normative data into the knowledge base is achieved through an extraction pipeline:

- The system stores norm-specific instructions and rules, referred to as a “framework”.
- The extraction is done through the Gemini API due to the strong capabilities of their LLMs.
- The resulting schema encapsulates the information of the documents and is extendable for other norms due to the use of MongoDB.

Results

Core Features

Compliance AI assistant:

A chatbot that gives step-by-step guidance using RAG on the requested controls.

Compliance verification engine: An AI system that analyzes submitted evidence relating to a control and verifies its compliance with the acceptance criteria, with explanations, citations and confidence scores, that can be further explained inside of a new chat.

Conclusion: We developed a scalable schema and extraction pipeline for processing normative documents, along with a set of interfaces that use this data combined with Large Language Models to give valuable aid to companies seeking compliance. The goals for this project were met successfully.
